

Supplementary Figure S2. Phase I-Launch relative success (RS) of pQTL-supported versus unsupported target-indication (T-I) pairs by therapeutic area. RS was computed within each therapeutic area using the Katz log method. Therapeutic areas were included if they had at least one pQTL-supported T-I pair entering Phase I and at least one pQTL-supported pair that reached launch (RS > 0). Nine therapeutic areas were excluded: six with no pQTL-supported T-I pairs at Phase I (endocrine, immune, infection, ophthalmology, other, psychiatry) and three with pQTL-supported pairs but no launches, yielding RS = 0 (neurology, oncology, signs/symptoms). The background was restricted to T-I pairs where the target was measured on at least one proteomic platform (Olink or SomaScan). Supported = $A[G]/S[G]$ = launched/Phase I among pQTL-supported pairs; Unsupported = $A[!G]/S[!G]$ = launched/Phase I among pQTL-unsupported pairs. Error bars: 95% CI (Katz log method).
