

Supplementary Figure S1. Study design flowchart illustrating the two analytical paths: (1) systematic identification of pQTL-supported target-trait pairs through Mendelian randomization of eight proteogenomic datasets against ~8,000 complex trait GWAS, and (2) enrichment analysis comparing clinical success rates of pQTL-supported versus unsupported target-indication pairs using the Minikel et al. framework. Numbers at each step indicate the count of datasets, traits, associations, or T-I pairs retained after applying the indicated filters.
