

Supplementary Figure S3. Relative success (RS) of pQTL-supported versus unsupported target-indication (T-I) pairs by clinical phase transition. RS was computed separately for each individual phase transition (Preclinical > I, I > II, II > III, III > Launch) and for cumulative transitions (Preclinical > Launch, I > Launch). The denominator for each transition includes only T-I pairs that entered the starting phase. The background was restricted to T-I pairs where the target was measured on at least one proteomic platform (Olink or SomaScan). Supported = $A[G]/S[G]$ = succeeded/entered among pQTL-supported pairs; Unsupported = $A[!G]/S[!G]$ = succeeded/entered among pQTL-unsupported pairs. Error bars: 95% CI (Katz log method).
